The Role of Land-Cover Change in High Latitude Ecosystems:
Implications for the Global Carbon Cycle

Global Change in High Latitude Ecosystems
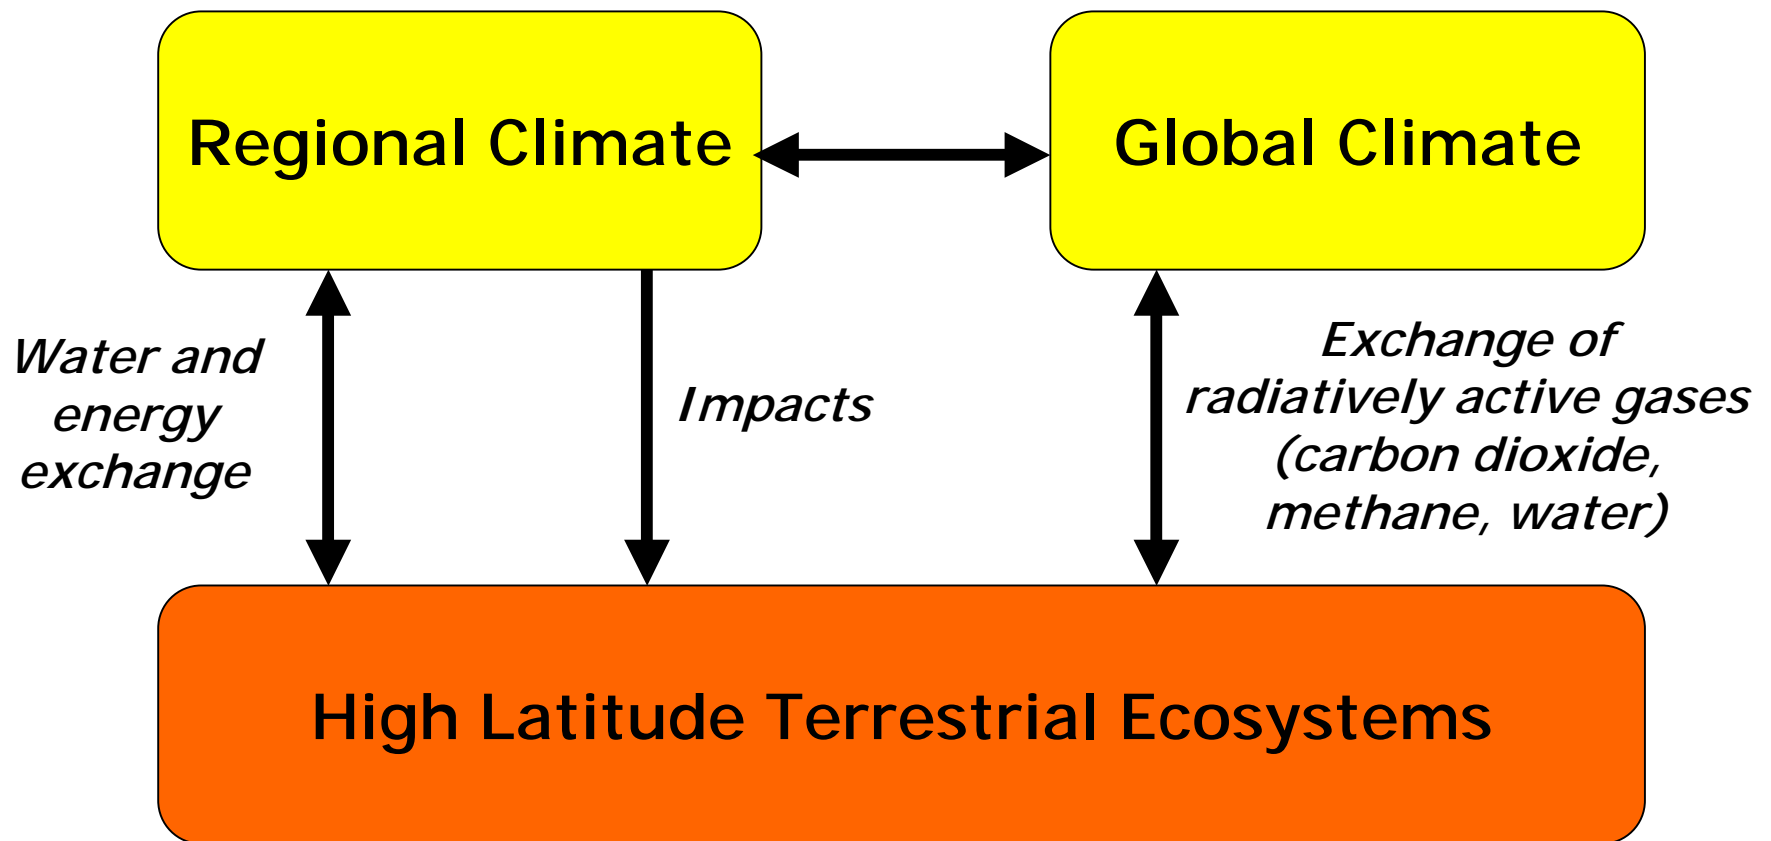

Participants

- **A. David McGuire (PI, UAF)**
- **Dave Verbyla (Co-PI, UAF)**
- **Jerry Melillo (Co-PI, MBL)**
- **Rose Meier (UAF)**
- **Dave Kicklighter (MBL)**
- **Matt Macander, Cherie Silapaswan, Aaron Woods, Qianlai Zhuang, Dorte Dissing**
- **Scott Rupp, Terry Chapin, Tony Starfield**

Project Goals

- **Develop prototype spatially explicit modeling framework to elucidate how land-cover change in high latitude ecosystems influences carbon storage**

- **Apply modeling framework to assess sensitivity and uncertainty of terrestrial carbon storage responses in high latitude ecosystems**
  - **Historical responses**
  - **Future responses**

Strategy

- **Focus on Alaska**
- **Develop historical transient land cover**
- **Develop components of modeling framework**
- **Application of modeling framework**
  - Retrospective analyses
  - Prognostic analyses

Why Alaska?

- **Substantial development over last 30 years**

- **Timing and extent of disturbances known**

- **Major disturbances include fire, logging, and insect infestation**

- **Vegetation replacement may be occurring**

- **Climate change may be affecting vegetation dynamics and the frequency and extent of disturbances**

- **Process-based research (taiga/tundra LTERs)**

Development of Transient Land Cover

- ## Focus: 4 regions in Alaska plus Global
  - ### Tanana River Valley - fire and logging
  - ### Copper River Valley - insects and logging
  - ### Seward Peninsula - vegetation dynamics and fire
  - ### North Slope - vegetation dynamics
  - ### Global - agricultural land use
- ## Change detection
  - ### Aerial Photography
  - ### Landsat MSS, TM
  - ### AVHRR
 - ### Ancillary Data Sets

Study Regions in Alaska

**North Slope:
Tundra Transition**

# Change Detection in Interior Alaska

- **Theoretical Issues (GCP's, Grain Size, Classes)**

- **Firescar Database 1950-1997**

- **Comparisons with Landsat Imagery**

- **Detailed Analysis of Land-Cover Change: 1983 Rosie Creek Fire**

  - **Pre-fire Air Photos and Landsat MSS Imagery**
  - **Immediate Post-fire Air Photos and Landsat TM Imagery**
  - **Decadal Post-fire Air Photos and Landsat TM imagery**

Potential Bias in Land Cover Change Estimates Due to Positional Errors

- Bias can occur at any spatial scale

- False change may exceed real landscape change
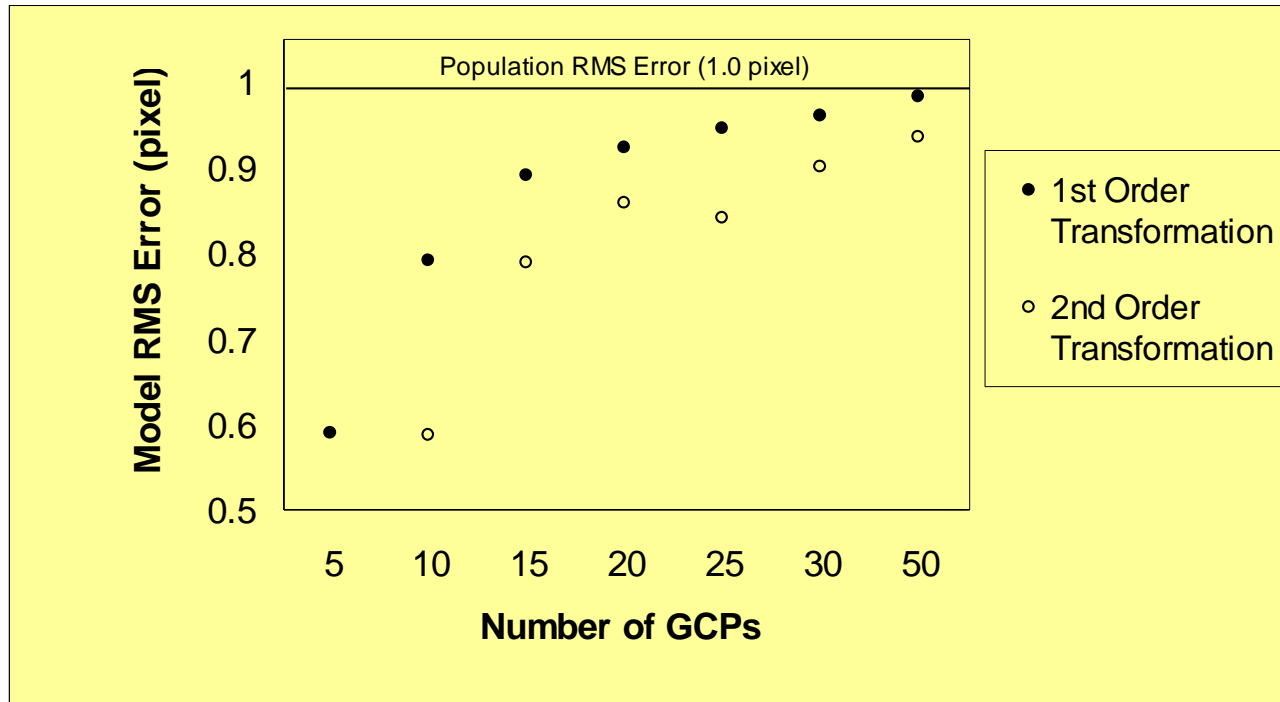

Subpixel rectification error may be optimistic:

- model error varies with GCP sample size
- model error varies with transformation order
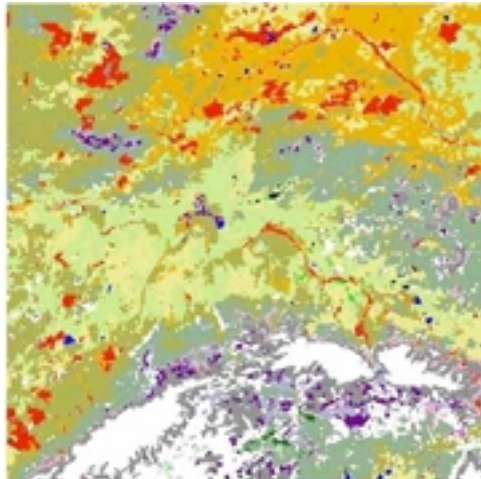

**Landsat TM 20 Classes**

Landsat TM 6 General Classes

10 KM

AVHRR 20 Classes

AVHRR 5 General Classes

500 KM

	20 class, 25m pixel		20 class, 1km pixel		6 class, 25m pixel		5 class, 1km pixel	
	Co-registration RMS error	Percent Change	Co-registration RMS error	Percent Change	Co-registration RMS error	Percent Change	Co-registration RMS error	Percent Change
Trial#1	1.10	7.6	0.72	10.9	1.10	8.4	0.86	1.4
Trial#2	0.86	23.7	0.89	14.3	0.73	8.2	0.87	3.5
Trial#3	1.00	8.6	0.89	20.4	0.81	10.1	0.76	2.0
Trial#4	0.75	33.2	0.95	1.8	0.94	8.5	0.96	0.1
Trial#5	0.97	5.9	1.01	13.9	0.89	15.0	0.96	0.5
Trial#6	1.06	9.7	0.94	7.1	1.02	2.2	0.97	2.7
Trial#7	0.93	8.8	0.86	6.6	1.01	10.6	0.96	1.2
Trial#8	0.71	16.1	1.01	5.4	1.09	5.8	0.99	0.6
Trial#9	0.86	4.2	1.00	10.1	1.01	4.4	0.93	1.1
Trial#10	0.90	19.8	0.82	8.4	0.87	14.2	0.96	0.9

- **Landscape metric of heterogeneity not useful; bias in landscape change varied by trial**

- **Bias in landscape change was generally more significant with heterogeneous landscapes**

- **Subpixel co-registration may not solve the problem**

Change Detection in Interior Alaska

- Theoretical Issues (GCP's, Grain Size, Classes)

Vegetation Regeneration after the 1983 Rosie Creek Fire (Bonanza Creek LTER)

Developing a Predictive Model of Post-fire Regeneration Classes

• Remote sensing as primary data source: aerial photography and satellite imagery obtained before and after the fire.

•On most burned forest sites in Interior Alaska, shrub regeneration dominates a decade after the fire. What conditions are most likely to lead to alternative successional trajectories?

Air Photo Class	Pixel Count	Shrub Regen. Proportion
Pre-fire Hardwood	967	0.903
Pre-fire Muskeg	5304	0.609
Pre-fire Spruce	4466	0.549
Light Burn	2262	0.743
Moderate Burn	6976	0.508
Severe Burn	1499	0.888

•Topographic position, salvage logging status, and field measurements of biomass, soil, and permafrost will be used as additional explanatory variables.

Why is Modeling Permafrost Dynamics Important?

• The dynamics of permafrost influences the physical environment, ecosystem function, ecosystem structure, and the disturbance regime

• The effects of disturbance on permafrost dynamics influences vegetation trajectories after disturbance

• Permafrost is warming in many high latitude regions

• Areas of discontinuous permafrost are most vulnerable to melting and are also regions of higher population density

• Thawing of permafrost has important impacts on humans in high latitude regions

- Y1989

0   400   800 km
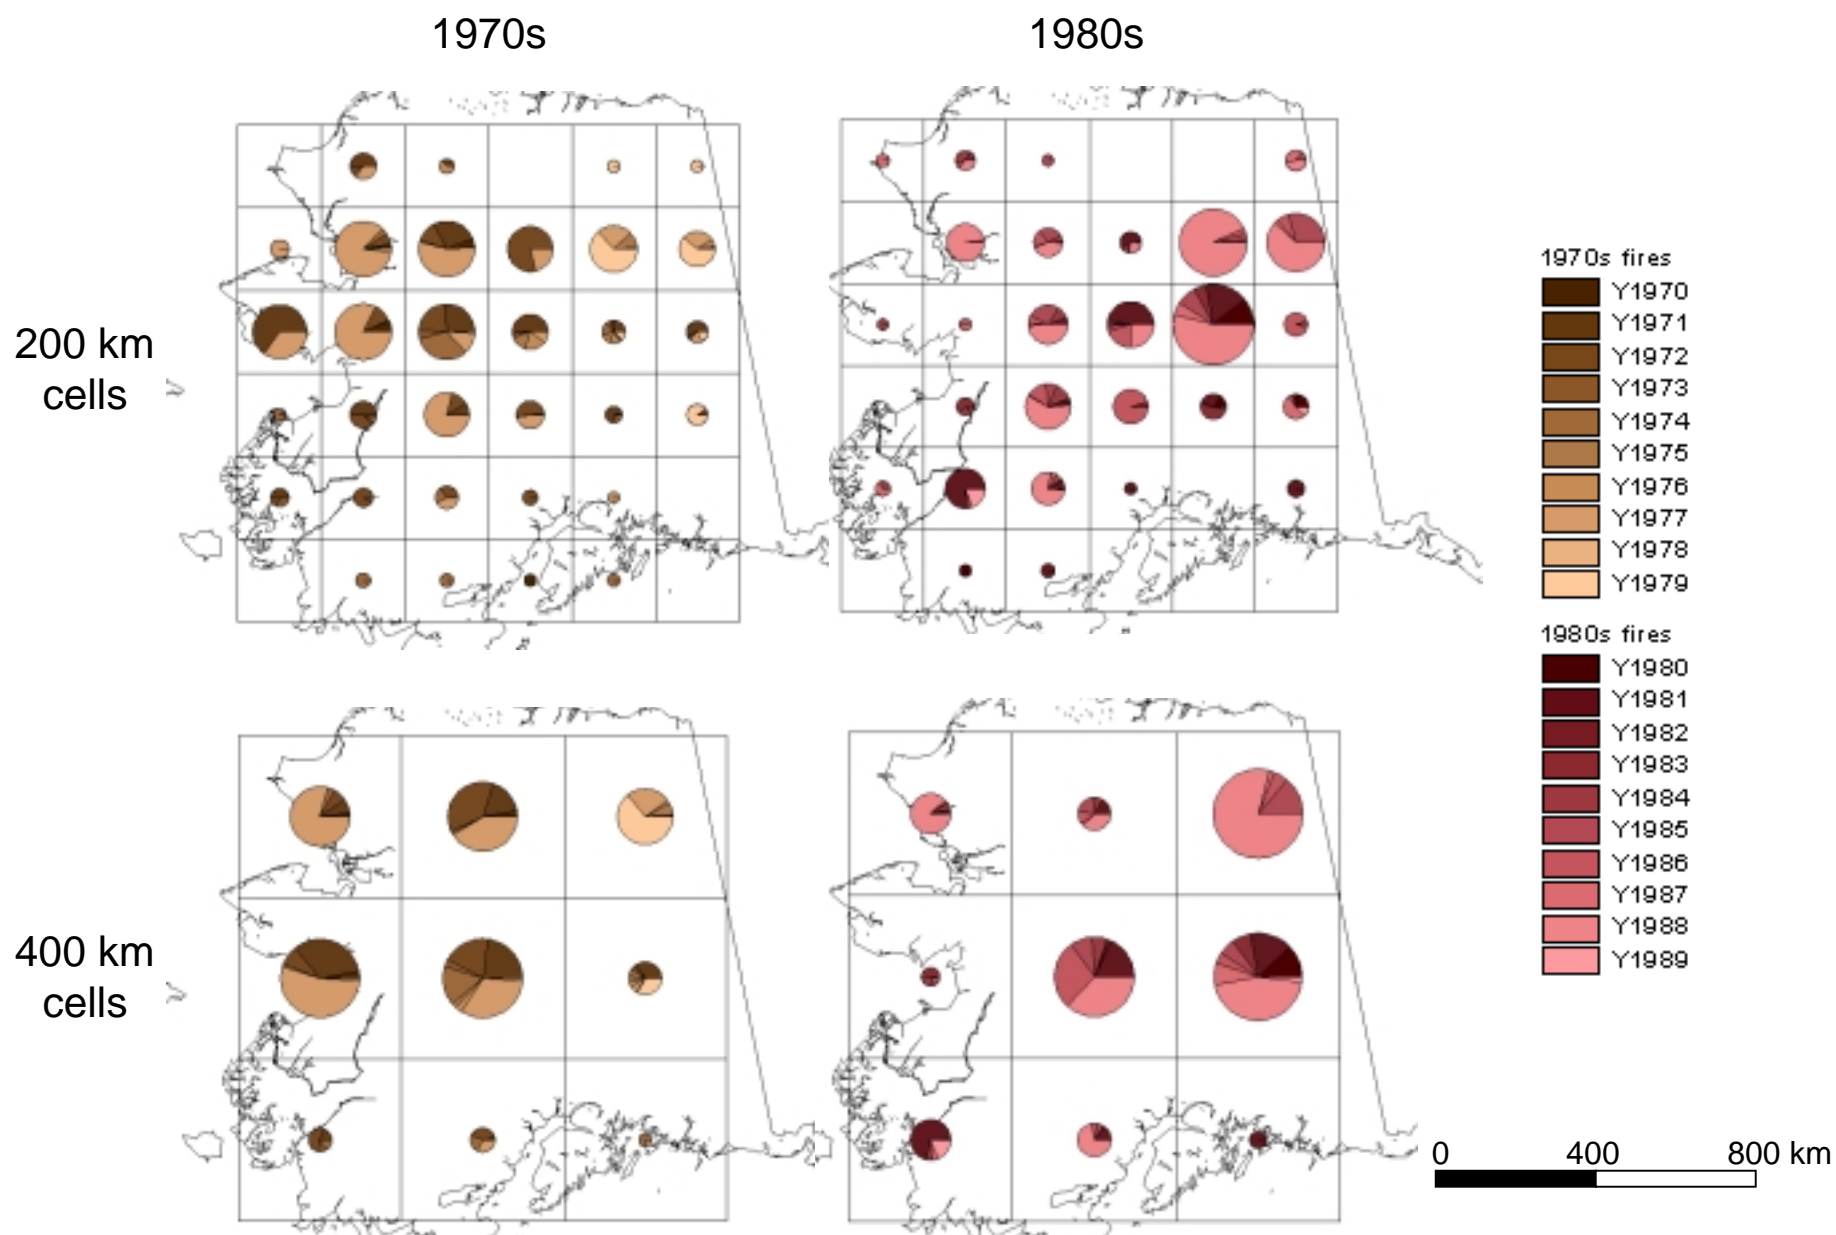

Annual Area Burned as a Proportion of Decadal Area Burned at Regional Scales in Alaska

Cell Size vs. Proportion of Decadal Area Burned in Maximum Fire Year
(Only Includes Data from Cells where >1% total area burned in the decade)

• On average, 50-80% of the area burned in a decade is burned in the maximum fire year.

• Within smaller regions, the impact of the largest fires and fire years is greatest.

• Fire regime dominated by very large fires and fire years.

Evaluating the role of interannual climate variation in proportion of area burned at half-degree resolution:

Logistic Regression Model:

Proportion Burned = e^{LP} / (1 + e^{LP}) where

$LP = -14.939 + 0.0896T_{MAY} + 0.6478T_{JUNE} - 0.00933 SNOWPACK_{MAY}$

- The model overestimates number of cells with small burns and underestimates number of cells with large burns

- Aggregating results to the state scale, the model explains 33.7% of the interannual variance in area burned across Alaska

- Over 47 years, the model predicts area burned within a few km^2

Evaluating the role of fire history:

We examined the pattern of burning in fire-history cohorts that existed in 1990:

	Burned	Unburned
Previous Burn > 40 years ago	135	1675
Previous Burn <= 40 years ago	54	1115

- Of 2979 cohorts in 1990, 60.8% had not burned in last 40 years
- Of cohorts burned in 1990, 71.4% had not burned in last 40 years
- Chi-square Test: P = 0.0025

Solar Radiation Heating the Ground

▶ **Radiant Surface Temperature Vegetation / Topography**

The hottest surfaces support updrafts (H1a)

Significant differences in surface temperatures between vegetation types (H1a)

Homogeneous Surfaces

Surface temperature of burn scars differ significantly from surroundings (H1b)

Heterogeneous Surfaces

▶ **Wildfire Burn scars**

Strong surface heating will produce isolated "fair-weather" Cumulus clouds (H2a)

Landscape induced mesoscale circulations will produce organized convective complexes (H2b)

▶ **Isolated "Fair-weather" Cumulus Development**

▶ **Organized Cumulus Development**

Isolated "fair-weather" Cumulus over homogeneous, hot surfaces is not expected to develop into Cumulonimbus (H3)

▶ **Cumulonimbus Development**

Cumulonimbus form mainly over heterogeneous landscape due to induced mesoscale circulations (H3)

Lightning strikes serve as indicator of thunderstorm development (H3)

▽ **Lightning Strikes**

Significant Results

- Theoretical exploration of factors that influence the level of false change detection in estimates of land cover change.

- Making progress in developing a methodology to estimate decadal scale land-cover change in high latitude ecosystems.

- Progress in modeling effects of climate on permafrost dynamics, ecosystem function, and aspects of the disturbance regime.

- Progress in coupling models of ecosystem structure and function in high latitude ecosystems.

- Progress in modeling the role of elevated atmospheric CO_2, climate, and agricultural land use in the global carbon cycle.

Policy Implications

- Relevant to international negotiations with respect to controlling the concentrations of radiatively active gases in the atmosphere.

- Providing support for the use of spatially explicit and temporally explicit vegetation, disturbance, and climate data in the Alaska Regional Assessment.

- Conducting pathfinding research for the application to Alaska of the models in the Vegetation/Ecosystem Modeling and Analysis Project (VEMAP), which is an important component of the National Assessment.

- Regional and global analyses will contribute to the IPCC assessment process.

- McGuire et al. Historical and projected patterns of carbon storage on the Seward Peninsula, Alaska: The role of changes in atmospheric carbon dioxide, climate, simulated fire, and simulated vegetation dynamics.

- Rupp TS, Starfield AM, Chapin III FS (Submitted) A frame-based spatially explicit model of subarctic vegetation response to climatic change: comparison with a point model. Landscape Ecology.

- Rupp TS, Chapin III FS, Starfield AM (Submitted) Response of subarctic vegetation to transient climatic change on the Seward Peninsula in northwest Alaska. Global Change Biology.

Next Steps

- **Remote Sensing and Spatial Data Sets**

- **Modeling**

- **Human Dimensions**

Next Steps

Remote Sensing and Spatial Data Sets:

- Better automation of change-detection methodology

- Application of methodology to broader region (Alaska and beyond)

- Use of new technologies/data - MODIS, LANDSAT 7

Next Steps

Modeling:

- Continued development of individual modeling components

- Focused effort on a predictive model of the fire regime

- Vegetation dynamics based on both population processes and biogeochemistry

- Comparison between forward and inverse modeling approaches

- Incorporation of human dimensions

Next Steps

Human Dimensions:

- **Fire control policy**

- **Direct costs of fire control**

- **Non-ecosystem related costs of fire**

- **Ecosystem-related costs and benefits of fire**

- **Demographic and economic conditions**
